

The input XML document may be either a query document or a data document. A query document contains attributes, which when synthesized by the '**sqlMapper**' class will be used to compose a sql query that can be issued to the database from the '**issueQuery**' class.

A data XML document contains data consistent with the objectToBeLoaded.dtd or that is passed to the 'plotWriter' class which will either insert the data into the database or update database records with the data contained within the document.
